Neurobehavioral History Questionnaires are popular and well reviewed forms that organize psychosocial and medical information to ensure a thorough understanding of the patient. They document the thoroughness of your assessment and ensure that critical information is not overlooked, which is vital in medico-legal situations. Sections include Review of Symptoms, Medications, Family History grid, Education and Work History. Both short (4 pages) and extended (12 page adult, 8 page child) forms are available.

Signs and Symptoms Questionnaires elicit patient or family concerns and provide severity ratings for each problem. The format helps differentiate pre-existing problems from new problems. These forms provide a tool for organizing presenting concerns and ensure that important issues are not overlooked. They help focus your assessment so you can determine the validity of the reported complaints. The child questionnaire is for school aged children. Areas assessed include Executive Functions, Language, Non-verbal Skills, Memory, Attention and Self-regulation, Motor and Sensory, Behavior and Mood. The forms have a section to help assess over-reporting.

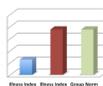

Bicycle Drawing Test New for 2018

A revision of the 1994 scoring system (Greenberg, et al., Assessment, Vol. 1, No. 1, 89- 101, 1994) includes multiple sections (Parts / Complexity, Motor, Visuospatial, and Mechanical Reasoning) to thoroughly describe the drawer's ability. Includes both a Bicycle Drawing from Memory scoring system and a new copy phase. The manual is available later in 2018. Contact us for a manual draft.

The Tens Test

The Tens Test assesses sustained and selective auditory attention. It is an effective alternative for the adolescent, adult or elderly patient who may have difficulty tolerating stressful tests such as the PASAT. It is a validated and reliable eight-minute test that presents spoken digits at three speeds and the individual must indicate when two adjacent numbers add to 10. Includes scoring form and manual with reliability, validity data and norms.

Illness Index

It is important to know how patients appraise their illness or injury. Perception of illness, also known as illness burden, or Health Related Quality of Life, is a significant psychological factor that is related to treatment compliance, satisfaction with medical care, depression and morbidity. These scales measure perception of illness from the perspectives of the patient, healthcare provider and family member. Comparing the protocols yields valuable clinical hypotheses (described in the manual).

REVIEWS OF THE HISTORY FORMS

"Comprehensive...efficient, organized and thorough, reducing the likelihood that pertinent information will be overlooked."

Anthony Springer, PhD A Guide to Adult Neuropsychological Diagnosis

"They ask the type of questions I would ask and they provide a very nice permanent record in the chart of a patient's history."

Erin D. Bigler, PhD Past President, National Academy of Neuropsychology

"...allow the clinician to collect comprehensive historical information in a systematic way...serves to reduce subjective aspects of the interview and increase diagnostic accuracy between clinicians."

Arthur D. Williams Ph.D. Practice of Forensic Neuropsychology: Meeting the Challenges in the Courtroom, Springer Books, 2004
